Anatomy Of The Mandible

The Mandible Joe Iwanaga, R. Shane Tubbs, The fine osteological and radiological anatomy involved in dental and oral surgery has progressed greatly in recent years especially in the field of dental implants In dental implant surgery the maxilla and mandible are the operative fields The frequent complications of dental implants on the maxilla are bleeding and iatrogenic maxillary sinusitis but these are less likely to be life threatening injuries However dental implant surgery of the mandible can lead to serious complications such as mental nerve paresthesia and airway obstruction due to hematoma Therefore knowledge of anatomical structures relevant to the mandible is significant and the authors have a long history of investigating normal anatomy and anatomical variations of the mandible When the dentist needs a comprehensive photographic review of the anatomy focusing on the mandible including well described anatomy and rarely shown variations with both gross and radiologic observations this book will prove to be a valuable resource that is useful for surgery It is the first book of its kind devoted to the osteological and radiological anatomy of the mandible for dentists and oral surgeons It will satisfy the growing demand in the field of surgery and education and will be welcomed and timely for clinicians and trainees in the field It will be of benefit to general dentists dental students and specialists and residents of periodontics dental implant prosthodontics and oral surgery as well as craniofacial surgeons anatomists plastic surgeons ENT surgeons head and neck surgeons medical students dental hygienists anthropologists and forensic specialists

Posterior Mandible Anatomy- Surgical Considerations in Relation to Bone Harvesting Procedures Fistarol Francesco, 2017

Background Autogenous bone is still considered one of the most predictable materials for reconstruction procedures in implant dentistry. Many bone harvesting protocols have been described in literature and mandibular ramus represents one of the most common location to harvest autogenous bone. Aim The aim of this study is to evaluate the anatomical characteristics of the posterior region of the mandible mandibular ramus and external oblique line and the surgical relevance of these anatomical characteristics related to the bone harvesting procedures. Methods and Material 50 retromolar sites providing from mandibular CTBs of patients 18 males 32 females which should be treated with mandibular autogenous bone harvesting and alveolar ridge augmentation were analyzed considering the donor site anatomies. For each retromolar site linear measures in cross sectional CT scans were taken to record perpendicular distances between the mandibular canal and the external bone walls. The mandibular canal lengths were also recorded. Results The mean value of mandibular canal lengths was 64.1 mm (range 55.0-70.0) and the median was 64.6 mm. Linear measures showed a characteristic trend: the distance from the mandibular canal and the vestibular bone wall is lower in the retro molar area than in the molar area, reaching values under 2 mm in 26% of cases. Although the distance between the mandibular canal and the crestal bone wall is higher in the retro molar area than in the molar area. Conclusions and Clinical implications There is less thickness of bone in the distal ramus area where the posterior vertical osteotomy of some bone harvesting procedure is performed. This could expose the inferior alveolar nerve to damage.

Atlas of Oral and Maxillofacial Anatomy Joe Iwanaga, R. Shane Tubbs, 2021-11-05. This comprehensive atlas featuring a wealth of top quality photographs of fresh cadaveric dissections is a superb guide to anatomic structures in the oral and maxillofacial region that will be an ideal aid in clinical practice. It has the important benefit of enabling readers to observe the anatomy from the same view as seen during invasive clinical procedures. This is critical for a better understanding of these procedures and surgical annotations are included as necessary. *Atlas of Oral and Maxillofacial Anatomy* is the first book of its kind to be devoted to the clinical anatomy of the region for dentists and oral and maxillofacial surgeons. It will satisfy the demand for such a comprehensive atlas in this field of surgery and will be welcome and timely for clinicians and trainees. Beyond specialists and residents in oral and maxillofacial surgery and general dentists, the book will be of value for craniofacial surgeons, anatomists, plastic surgeons, ENT surgeons, head and neck surgeons, neurosurgeons, dental students, medical students, dental hygienists and nurses working with dentists and oral and maxillofacial surgeons.

An Analysis of Anterior Mandibular Anatomy Using Cone Beam Computed Tomography: A Study of Dentate and Edentulous Mandibles

Roberta A Wright (D.M.D.), 2016

Statement of Problem The anterior mandible has conventionally been deemed as a relatively safe zone for dental implants due to perceived lack of innervation to the area as well as its relatively thick cortices and dense bone. However, with the evolution of cone beam computed tomography (CBCT), a number of anatomic challenges have been identified by clinicians that can lead to neuropathy and life-threatening hemorrhage if violated. The three critical anatomic structures in this area that pertain to implant placement are the sublingual artery (SLA), submental artery (SMA), and the mandibular incisive canal. Currently, there is a lack of knowledge regarding average measurements of these anatomic structures in relation to a specific non-variable landmark. Furthermore, it is not known if there are any significant variations of these anatomic structures in dentate and edentulous patients. While these structures may be identifiable on a CBCT scan, mandatory CBCTs are not required by practitioners in order to perform implant surgery in the anterior mandible.

Purpose To determine if standardized average values can be obtained for the sublingual artery (SLA), submental artery (SMA), and mandibular incisive canal (MIC) and if differences exist between dentate and edentulous patients.

Materials and Methods CBCTs of 125 edentulous and 100 dentate subjects were evaluated at the anterior mandible for incidence of visualization of the SLA, SMA, and MIC. Measurements of these three structures were also made from the inferior cortical border of the mandible to the superior border of each structure in order to gain average anatomical measurements. The cross-sectional shapes of anterior mandibles were also categorized, and prevalence of each shape in this sample was calculated.

Results The incidence of visualization of the SLA on CBCT was found to be 100% for edentulous subjects and 98% for dentate subjects. The SLA was located approximately 15mm above the inferior border of the mandible. The incidence of visualization of the SMA on CBCT was 94% for edentulous subjects and 88% for dentate subjects. The SMA was located approximately 5mm above the inferior border of the mandible. The incidence of visualization of the MIC on CBCT was 61% for edentulous subjects and 59% for dentate subjects. The MIC was found to be approximately 1.5mm in diameter at the lateral incisor and canine regions. The MIC was located approximately 11mm above the inferior border of the mandible in edentulous patients and approximately 14mm above the inferior border of the mandible in dentate patients. The edentulous mandibular ridge attained a buccal-lingual width of 6mm at a mean distance of 4mm below the ridge crest in this patient sample. A new classification system for the cross-sectional morphology of the anterior mandible was characterized and includes the following shapes: hourglass, ovoid, pear, sickle, and triangular. The pear was the most commonly visualized cross-sectional morphology among both edentulous and dentate patients.

Conclusions The sublingual artery and submental artery can be consistently identified in the anterior mandible using CBCT, both in dentate and edentulous patients. The SLA was located approximately 15mm above the inferior border of the mandible, and the SMA was located approximately 5mm above the inferior border of the mandible. The mandibular incisive canal was not consistently visualized. The cross-sectional morphology of the anterior mandible is diverse in dentate and edentulous mandibles, with pear shape being the most common in both situations. These findings should be taken into consideration when treatment planning for implants using CBCT or panoramic radiography.
